A MEMORANDUM REPORT

ON THE

ATHABASCA GOLD PROJECT

0F

359341 ALBERTA LTD.

By Kenneth Richardson, Prospector

۰.

August, 1990

THE ATHABASCA GOLD PROJECT

E PROJECT

An exploratory drilling program was carried our by 359341 Alberta Ltd., to inverse the sources of gold reported on the east bank of the Athabasca River in northern Alberta. See Index Map. A Brief report of the results secured and comments theron are hereinafter set forth.

The project was started February 1989 and was completed approximately April 28, 1989. Extensive examination was made of the area and site was choosen for drilling of 1 e the old churn drill holes reportedly drilled in 1911.

The drill irea is situated near a block of Metallic Mineral Claims in Township 95 and 96, Range 10 and 11, West 4thM, approximately 48 miles north down the Athabasca River from Fort McMurray, in the Province of Alberta. The Subject area is within the Athabasca Bituminous Sands area and the mining right were coexistant with previously granted lease permits for the development if the bituminous sands.

The drilling equipment, camp fixtures and supplies were trucked in by the winter road to Fort Chipewan and the west down siesmic lines conveniently located to the drill site. Very little vegetation was distrubed at any time.

TOPOGRAPHY AND COVER

The surface of the area is peneplaned to fairly even level approximately 65 metres above the Athabasca River except where incised by numerous steep walled meandering tributiry streams. The elevation of the river, (Low Level), is taken from Ell's map as being 231.64 metres, while the of the immediate drill area on the upper level surface id 295 metres above sea level.

The land area has a dense cover of brush and soft wood leaf trees, mostly birch and alder, with occasional stands of spruce trees that have escaped the periodic forest fires. In some places dandy ridges, remnants of glacial eskers have a park-like grassland vegetation. The road to Bitumint follows along remnants of an esker for about 3 of the 5 mile length.

NERAL GEOLOGY

•

74E/4,5

The Athabasca Oil Sands of Cretaceous Age occupy the entire surface of One region. The oil impregnated sands of the McMurray formation from spectacular estimated to contain more the 300 billion barrels. The sands have been ally considered to be the largest known reservoir of oil. There are 2 bituminous sand formations in the region but the upper, the Clearwater, has been removed ary.

The oil sands are underlain by 800 ft. of limestone, shaley limestones, limy shales and limy muds, and a succession of gypsum and anhydrite beds, with some bituminous shales, to the Precambrian basement rocks. Diamond Drill Hole No. 1 was drilled with a 41 inch Tri-cone bit down to 218'. Cassing was the set and cemented in according to ERCB requirements. B.Q. core was taken from 218' to a final depth of 998' The rig was closed down several days for Easter and then stuck in hole for about 10 says at which time Barold of Canada Ltd. was called in to give chemical and technical service for 2 days. Completion of Coring and logging was April 28, 1989.

SUMMARY OF DRILLING RESULTS

LL HOLE

The purpose of the drill program was to locate, test and develop the source of gold purportedly found in the area. The location was chosen as being the most likely spot. From the data secured the following deductions seem to be logical:

1. No evidence of gold mineralization was found to be present other that what may be normal consentrations.

2. No Evidence of any quartz veins was found in the sedimentary formations.

3. No evidence was found of any structural breaks, faults, brecciat, zones, silicified zones, or rones showing effects of hydrothermal alertation.

4 The work done so far in the confined area does not conclusively prove that there is not gold present in the vicinity.

SEDIMENTARY ROCKS

Approximately 1,000' of sedimentary rock is reported by other holes willed in the area to lie on the Precambrain granite basement rocks in this area. At the surface is found the oil impregnated sands of the McMurray Formation, Lower Cretaceous in age, which is about 205' thick in the drill area.

The McMurray is described as being arenaceous and of rather a coarse grain and varies from massive to thick bedded. The lower part is in many places bross-bedded, with beds dripping 5 to 40 degrees. There is no system to the succession of rich and lean bituminous sand beds in the sections through the sand formation which may contain from 0 to 305 by volume of heavy oil. Apparently the sand particles are surrounded by a film of water and the oil does not wet the sand, fortunately, making it possible to obtain a fairly high percentage of recovery of oil in the processing operations.

The sand tormation contains irregular concentrations of marcasite (iron-sulphide), and where these consentrations have oxidized at the surface, stones and slab, of "irrectors," are found.

The McMurray oil sand formation lies unconformably on an old erosion surface of Upper Devonian limestones, shales, limy shales, shaly limestones and limy mods. Devonian time was marked by a submergence that spread the Appalachian seaway westward to the Mississippi Valley, and soon brought another vast Arctic flood creeping southward across western Canada by wiv of the Mackenzie Valley region in a seaway nearly 1,000 miles wide. The seaway, were barely awash, however, and at carious times great arms of the sea were cit off and long periods of evaporation of the sea waters took place, laying down alternate layers of evaporates of gypsum, salt and potash brines. The Bitumont area was near the high water mark, however, and received only gypsum evaporites. McMurray has 200' of salt in salt wells but the bed thins out 26 miles north of McMurray. Further east in Saskatchewan over 1200' of salt was deposited as well as potash brines.

In such arms of the sea brackish water favored the growth of low forms of marine organic life which became buried in the marine muds and formed the bituminous (petroliferous) shales that are found in the zone from 767 to 928 ft. Such periods were interrupted frequently by the periods of evaporation as shown by the frequent bands of gypsum. Oil and gas were formed in the bituminous shales and have mostly migrated elsewhere. It seems possible that the oil now found in the Athabasca Tar Sands has migrated from its sources of formation at least partly from the underlaying Devonian shales from dip down slopes many miles to the east southeast and south, for these formations thicken and deepen in those directions.

There is some question question of the age of the lower part of the secimentary formations for during the Middle Devonian and Upper Silurian apparently the same conditions prevailed and with no apparent unconformity of physical expression. Possibly a careful study of the fossil remains would settle this question

PRECAMURIAN BASEMENT ROCKS

The Precambrian rocks that make up the Cana for Shield from the bedrock for a land area of about 1,864,000 sq. mi, in Canada. The western edge of it surface outcrop is about 40 to 70 miles northeast of the property and here it is covered with about 1,000 ft, of sediments. Where it is exposed to the northeast it is a meanly flat, featureless plain with gentle undulations. While the topography is somewhat featureless, the composition is a complex aggregation of highly metamorphised and deformed group of igneous instrusions, stock, dikes, sills, flows and remnants of altered sedimentary formations.

STRUCTURAL GEOLOGY

No evidence of any structure was noted in this area by the writer. It was stated that a fault displacement was visible along the river tank a few miles north of the property. (M.P. McDougall). According to Contribution 118, Kidd, 1951; and carrigy, 1959, state that the eastern margin of oil impregnation coincides with a major depression on the pre-Cretaceous erosion surface, which trends in a northwesterly direction. Also that at the northern end of this depression in the vicinity of Bitumont Township 96, Range 10, the Clearwater and McMurray formations have been folded into a basin formed by post-Cretaceous collapse of the limestone. This suggests that a major depression existed before the oil sands were deposited and that they collapsed later, folding the oil sands. More discussion of this subject will be given underthe subject GEOPHYSICAL PHENOMENA below.

Geologic history of the Precambrian Shield indicated that most of the oroge structural dislocations also took place during Precambrian time. Table down-, ting of blocks took place here and there during submicreances during bevonian Silurian and Cretateous time, but other than the depression mentioned in the above paragraph, none is known in this area. It is probable, however, that some fracturing took place. Presumably the land remained stable following the Post-Cretaceous uplift and it is believed that the even skylines represent the Tertiary peneplain that follower this uplift. The great glacial period some buckling for it is known that elastic rebound is still continuing in some areas.

The presence of some fractures in the area can be surmised from the presence of the water holes discharging hydrogen sulphide gas. Surface waters percolating downward carying organic acids and bacteria reduce the sulphates in the gypsum layers. There is no evidence that any of such fractures might have been subjected to the presence of any mineralizing solutions. On the other bot be conducive to making then evident at the surface.

GEOPHYSICAL PENOMENA

A copy of Sheet 74 E/4 of Geophysics Paper 440, being an Aero-Magnetic Survey, June to September 1952, by the Geophysics Division, Geological Survey of Canada, was obtained.

The expressions of magnetism are shown by contours on the map as recorded at flight altitude of 1,000 ft. above the surface. These variations are for the most part due to changes in the magnetic content of the rocks making up the basement, but may also be due to the distance to the basement and its altitude. Strong anomalies are probably due to an increased magnetic content, but small anomalies may be due to either or all of the above causes.

A considerable number of writers, Vacquier and others, have noted that when considerable geologic knowledge of a region is available, if applied correctly, interpretations of magnetic anomalies may yield information on , maximum depth of sedimentary cover, location of rock contact including faults, and location of probable areas of differenteation and of mineralization when a locality is underlain by igneous rocks. They further reflect that an isoanomaly map indicates the structural history of the region.

The Aero-magnetic Map indicates that the center of a synclinal trough of low magnetic intensity (1200 gammas), lies exactly// mile west pf the drill site. It strikes North 22 West and slopes upward slowly for 10 miles to the northwest, then steeply upward between magnetic highs of 3300 on the east and 2800 on the west. To the southeast its slope is gradual to 1560 at the bottom of the map area 4 miles south of Mildred Lake.

The property itself is on a gentle undulating magnetic ridge, 2200 to 2400, about 2 miles in width and trending northerly. To the east there are

- 4 -

several scattered oval shaped domes and depressions of small relief, 300 to 600 gammas.

It is thought by the writer that the major depression of the Pre-Creticeous erosion surface, followed by Post-Cretaceous collapse during which the oil sands were folded, as set forth in Contribution 118, was probably diagnosed from the interpretation of the Aero-Magnetic map. Nothing was mentioned however, about the structure which must have been necessary to have caused the Post-Cretaceous collapse of the limestone.

It is the writer's opinion that collapse could have taken place only from the leaching away of the limestones by solutions by solutions circulating through fractures, faults or shear zones, or from the leaching away of the gypsum by solutions circulating through the same structures. The simple truth is that if one takes place the other does also. It is clear that some fractures penetrate the gypsum layers reducing hydrogen-sulphide gas which bubbles to the surface from 3 wells known to the writer, all 3 of which are within the depression

It is known that there are no dislocations of such magnitude as to cause interruption of the oil sands. So that the structure deduced to be present is probably no more that a series of fractures. Neither do the contours show steep variations necessary to indicate faults of magnitude.

GENERAL COMMENTS

The possibility of finding gold in the limestones above the Precambrian surface has been a unexplainable enigma to the writer since the first examination of the property. This is nor considered any unsurmountable obstacle from finding one, however, for one has been found many times in places that have been "firsts" either in types or locations.

All of the well-known gold camps of Canada are found in a metallogenic province of the Percamprian Canadian Shield extending more than 2,000 miles from Great Slave Lake to eastern Quebec. It was thought by the writer that the best chance of gold occurrence would be from gold veins within the Precambrian rocks themselves or from placer deposits accumulated on top of them. To find placer gold on such surfaces, it would have been necessary to find some type of channels of accumulation.

The only evidence here of any metallization is the presence of marcasite in the tar and its mode of origin is rather vague. It may or may not have had any direct connection with mineralizing solutions of hydrothermal origin. The fracture system indicated to be occupying the zone marked by the magnetic movements of late Cretaceous and Tertiary Epochs could have furnished the tectonic and magnetic sources for miners, though there is little surface evidence that this has happened. In some notable instances slumps in limestone areas have been the loci where important ore bodies have been formed, i.e., the great zinc-lead deposits of the Mississippi Valley region. Pine Point, and others. Such ores frequently have marcasite and pyrite as gamme minerals. The hidden slumps are now traced out by geophysical methods, followed by geological study and exploration drilling. These methods have located important new lead and one iron ore deposit in southeastern Missouri within recent years.

In this case there are present two possible indicators of favorable conditions of one deposition, with several unfavorable. In the weight of geological evidence it is a bet, but not a very good one. Possibly it might warrant a thorough surface examination in the region from the mouth of the Ells River Westward for 3 miles in search for further indications of mineral-

PREVIOUS AND CONTEMPORARY DRILLING

By far the greatest amount of drilling in the area has been to test the oil sands, a subject beyond the scope of this report. A few wells were drilled to explore for oil in the underlying Paleozoic Formations with a few reaching the Precambrian; most of these wells are also beyond the scope of this report. However, one such well was drilled on the east side of the Athabasca R, 11 W4. It is designated Athabasca Oils Ltd. No. 1.. Certain details concerning it in a report by Allan (1920) differ from those in a report by Ells

	<u>Allan (1920)</u>	Ells (1926)
Date drilled	1911-12	1915
Depth to Precambrian	336.8 m (1105')	291.7 m (957')•
Total Depth	344.4 m (1130')	313.9 m (1030')

In addition Allan (1920) reported that the 25 feet of precambrian granite carried \$13.00 per ton in gold. At the then prevailing price for gold, this works out to 0.63 oz/ton. A statement (Appendix 4) sworn on January the 14th 1946 at Trumbull County, Courtland, Ohio apparently by one of the drillers of Athabaska Oils Ltd. No. 1 refers to two Auriferous quartz veins five feet apart, three and and seven and one half feet thick, in limestone at a depth of 907 feet (276.5m). Recent examinations of the area at the reported site of Athabaska Oils Ltd. No. 1 revealed casing from two wells: One (CD-1) less than 30 m and a second (CD-2) about 210 m, east of the bank of Athabasca River. CD-1 Fits the location of Athabaska Oils Ltd. No. 1 as reported by Allan (1920). Ells (1926), and a photostat of a Dominion well card. CD-2 appears to be some of the information given differs from that of Ells (1926). In all Athabaska Oils Ltd. drilled five wells in Ip. 96, R. 11 W4, but only No. 1 appears to Lave

During the period of 1962 10 07 to 1963 01 09 four holes were drilled for Scurry-Rainbow 011 Limited (Elstone, 1963) near CD-2 in order to check for the gold reported by Allan (1920) in Athabasca 011 Ltd. No. 1; only three holes reached the Precambrian.

In March 1986 Tanner Arctic Oils Etd. drilled a hole about 1.3 metres

- 6 -

south of CU-1 to a depth of 296.3 metres. It bottomed in 1 metre of coarsegrained re Precambrain granite. As far as is known the upper part of this hole was triconed with the core point not stated, but core recovery was good below 277.1 metres. Five samples from the cored interval are believed to have been submitted for assay with all gold concentrations in the low ppb range. No Analytical results of samples of cuttings from the known cored section have been reported; presumably none were sent analyses.

None of the depths to the Precambrain in the three 1962-63 holes and the one 1986 hole agrees with that reported by Allan (1920) for Athabasca Oils No.1, but are close to that reported by Ells(1926). If Bradly's sworn statement, apparently referring to Athabaska Oils Ltd. No. 1 is accurate, the gold appears to be in the methy formation, not in the Precambrain as

PROPERTY

The property consists of a Metallic Minerals Exploration Permit under agreement No. 6888060001 dated 1988 6 30 with a term of three years to 1991 7 9 and renewable for up to four additional years. This comprises the following Twp Sec Part A 11 096 f W.L10.L15 2 NE 11 12 W.L2.L7. It totals 512 hectares according to the legislated conversion factor used by Alberta Energy and Resources. It is held in the name of Kenneth Richardson

who was required to make a work refundable deposit of \$10.00 per hectards on \$5.120.00 for the first three years of the permit. If the renewed, assessment work at the rate of \$20.00 per hectare is required in the first renewal period of two years and \$15.00 per hectare in each of the second and third renewal periods of one year each.

Sufficient work has been done to keep all the property in good standing and cause the Alberta Energy and Natural Resources to make a refund of the \$5,120.00 to the permit holder Mr. Kenneth Pichardson.

The project has been a most interesting one, it is believed that the disclosures are sufficiently encouraging to warrant the completion of the program of drilling further holes.

	1
Respectfully submitted.	

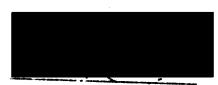

Kenneth Richardson Prospector 1. Kenneth Richardson, Prospector of the City of Edmonton in the Province of Alberta.

MAKE DATH AND SAY, THAT:

- I have knowledge of the work done on Metallic Minerals Exploration Permit No. 6888060001 as described in the report of which this statement is part.
- The expenses listed above were incurred in conducting work on Metallic Minerals Exploration Permit No. 6888060001.

Sworn before me at Edmonton. Alberta the 17 day of Gc y la 1990

-A A Commissioner for Uaths LEarses & Artedories Expily 7/11/92

> Poor Quality Original

1	481 601.		
	481 603. :		DOLOHITE: Interbedded light grey and medium grey dolomite. Occasional narrow bands of silty dolomite. Widely spaced beds of gypsum at following locations: 409', 534', and 577'. Locally there are narros fracture-fillings of white fibrous gypsum. 578'-603': Massivo dolomite - light grey with buff tinge locally.
	691 511	-	HALITE: Massive. crystal-clear salt. medium to coarsely grained.
	690.5.	1-	DOLOMITE-LINESTONE: Massive, dark and light grey dolomitic limestone with widely space narrow silty bands.
	710' - 719' :		DOLOWITE: Interbedded light to dark buif colored dolomite and medium to light grey dolomitic limestone. Bedding normal to hole axis.
0	719' - 730.5':		DOLOMITE: Thinly bedded (bandad) light and der: buff colored massive fine grained dolomite. Brecciated over last 2 feet.
	730.5' - 760' :		SILICIFIED LIMESIONE: Massive, very fine grained, light grey to white. Highly silicious. Widely spaced irregular fragments of light to medium brown, dolomitic limestone.
	760' - 770' :	-	DOLONITE & LIMESTONE: Silicified, narrow bands medium grey and light to medium brown dolomite and ilmestone with bands of gypsum and shale.
	770' - 776' :	-	GYFSUM: Intermixture of brown, light and dark grey, fine to medium grained gypsum.
	776' - 833.5';		DOLONITE: Interbedded massive and thinly bedded buff., medium and dark brown, fine grained dolomite. Bedding normal to hole amix. 812' - 833.5': Fragmental dolomite, various sized and shaped fragments ranging in size from 2 m.m. to 3 cm. across. Colors range from dark grey to buff to
			dark brown within a medium to dark brown dolomite groundmass. The fragments range from sharply angular to sub-rounded, elongate and rounded.

.

2.50 10. 3

.5' - 837' :

SHALE: Dark brown to black, fine grained shale with narrow quartz bands and thin scame of pyrite. There is a 5" seam of very fine grained, mansive pyrite at about 870 .

SPALE with large fragments of LINESTONE: Dark brown to black shale with large (up 837 . - 855' 1 to 3") rounded fragments of dark arey 1imestorr.

INTERBEDUED STLICFOUS LINESTONE, SHALE and - 888' : 355. DOLONITE: Mixture of medium brown, light and grey shale limestone, and buff colored delemite. Fine to very fine grained. "merous carrow fracture filling of white. fibrous sypsum. Bedding normal to hole axis.

SPALE: Medium to dark grey, fine grained. - 931 1 888' maneive shale. Occasional 1/4" wide fracture filling of white. fibrous cypsum.

SHALF. Fine to modium : sined with - 963' 1 931 . ertennive dark reddish brown limonitic staining. Wire spaced zones, up to 3" across which are not stained - here the shale is light greenish grey color. Numerous narrow fracture fillings of white fibrour cyreum, also bands up to 7" across, of fibrous synsum. Section becomes sandy towards botten.

963' - 983.5':

983.5' - 998'

ERE-CAMBRIAN BASEMENT: Gneissie red foldspar and dark preen ferro-magnesian mineral internized. The Celdspar is course grained. Locally heartitic particularly along shear surfaces. The lest 1 foot contains much white, milkly quortz and is less gneissic.

ARKOSE: Dark reddish brown, sandy

groundnass with various sized angular fragments of feldeper. Zenes of red hematitic staining. Locally vuggy.

998'

END OF HOLE.
