DISCLAIMER
By accessing and using the Alberta Energy website to download or otherwise obtain a scanned mineral assessment report, you (“User”) agree to be bound by the following terms and conditions:

a) Each scanned mineral assessment report that is downloaded or otherwise obtained from Alberta Energy is provided “AS IS”, with no warranties or representations of any kind whatsoever from Her Majesty the Queen in Right of Alberta, as represented by the Minister of Energy (“Minister”), expressed or implied, including, but not limited to, no warranties or other representations from the Minister, regarding the content, accuracy, reliability, use or results from the use of or the integrity, completeness, quality or legibility of each such scanned mineral assessment report;

b) To the fullest extent permitted by applicable laws, the Minister hereby expressly disclaims, and is released from, liability and responsibility for all warranties and conditions, expressed or implied, in relation to each scanned mineral assessment report shown or displayed on the Alberta Energy website including but not limited to warranties as to the satisfactory quality of or the fitness of the scanned mineral assessment report for a particular purpose and warranties as to the non-infringement or other non-violation of the proprietary rights held by any third party in respect of the scanned mineral assessment report;

c) To the fullest extent permitted by applicable law, the Minister, and the Minister’s employees and agents, exclude and disclaim liability to the User for losses and damages of whatsoever nature and howsoever arising including, without limitation, any direct, indirect, special, consequential, punitive or incidental damages, loss of use, loss of data, loss caused by a virus, loss of income or profit, claims of third parties, even if Alberta Energy have been advised of the possibility of such damages or losses, arising out of or in connection with the use of the Alberta Energy website, including the accessing or downloading of the scanned mineral assessment report and the use for any purpose of the scanned mineral assessment report so downloaded or retrieved.

d) User agrees to indemnify and hold harmless the Minister, and the Minister’s employees and agents against and from any and all third party claims, losses, liabilities, demands, actions or proceedings related to the downloading, distribution, transmissions, storage, redistribution, reproduction or exploitation of each scanned mineral assessment report obtained by the User from Alberta Energy.

INTRODUCTION

Quartz Mineral Exploration Permits 132, 133 and 134 are situated in the Northeast Corner of Alberta. The areas of the permits are 40,000, 49,920 and 49,920 acres respectively. The permits were taken to cover favourable structures in an area where uranium mineralization is known to occur.

LOCATION AND ACCESSIBILITY

The permits lie about twenty miles north of Fort Chipewyan. Permits 132 and 133 are bounded on the east by Lake Athabasca. These permits embrace about 9 miles of shore-line. The permits are at a latitude of about 59° 05'N and longitude 111° 00'W.

Numerous lakes within each of the permit areas provide easy access to float-equipped aircraft based in Fort Chipewyan (distance of about 20 miles), Fort McMurray (150 miles), Fort Smith (75 miles) and Uranium City (80 miles). Much of the eastern part of permits 132 and 133, and the southern part of permit 134 is accessible by boat from Fort Chipewyan. All the ground in each of the permit areas is easily accessible by foot from camps located on the numerous lakes.

GEOLOGY

The Northeast Corner of Alberta is entirely underlain by Precambrian metamorphic rocks. Metamorphic grades vary regionally and extend through the range from greenschist to upper amphibolite facies, and possibly to granulite facies (based on the work of Godfrey, Alberta Research Council, 1958-68).

The major structural features of the Precambrian of NE Alberta and NW - Saskatchewan are shown on Map 2. This is a compilation based on published reports by the following governmental offices: - Research Council of Alberta, Geological Survey of Canada, and Saskatchewan Dept. of Mineral Resources.
Localization of Uranium deposits - Uranium City and NE Corner

Uranium City Area

Intensive study by many geologists in the Uranium City area points to the following common denominators in the control of uranium mineralization.

Faulting - The approximately twenty mines which have been in operation, together with the many uranium occurrences, demonstrate a very close association with shear zones and minor faults which tie in with the major structures. Broad mylonite belts are associated with the NE-SW striking faults, and there is evidence to suggest that the uranium is genetically related to the process of mylonization. The intersections of faults striking E-W with faults striking NE-SW are statistically, particularly favorable loci for uranium.

Folding - Dilatancies along the axes of minor folds serve as structural receptors for mineralization in several mines in the area (e.g. Eldorado). In each such case the folds are in close proximity to faults and, therefore, constitute a structural control secondary to the fault.

Lithology - There does not appear to be any consistent lithological control for uranium in the Beaverlodge Area; the host rocks span almost the complete range of lithologies found in the region. Most uranium deposits are found in the 1820-2200 million year old (Baadsgaard$^2$) Tazin group of gneisses and metasediments. The Tazin rocks are regionally metamorphosed and the grade of metamorphism ranges from greenschist to granulite facies.

NE Corner

Radioactive occurrences in the NE Corner have been known since at least 1953 when a discovery was made north of Fidler Point (Fishing Lake). Godfrey has noted many radioactive occurrences while carrying out detailed mapping of the extreme NE corner during the period 1958 - 68. The occurrences are noted in Preliminary Report 58-4 (Research Council of Alberta), which covers an area of only between 5% and 10% of the Precambrian of NE Alberta. The following are the three most notable occurrences found by Godfrey.
1. On the Southwest arm of Andrew Lake radioactivity of 6 times background was noted in biotite schist and feldspathic quartzite. The full extent is not known. This ground is held by Rapid River Mines (see attachment).

2. A level of radioactivity 4 to 5 times background is associated with an occurrence at Spider Lake (Godfrey) and may extend for a strike length of about 2 miles. Grab samples assayed as follows: 1.03%U - .69% Mo; 3.93%U - 1.03% Mo; 3.29%U - 1.40% Mo. This property is covered by a permit held by McIntyre Porcupine Mines Ltd.

3. Numerous occurrences have been found in the vicinity of Cherry Lake. One of these radioactive occurrence continues for at least 150 feet along strike and 400 feet across strike. This ground is held by McIntyre.

The three occurrences cited above occur in metasediments.

At least three important uranium occurrences are documented in the area outside that covered by Godfrey. One of these, the Fishing Lake discovery, occurs in granite, granite gneiss and pegmatite (see attachment). High grade uranium over narrow widths has been reported for the Leggo Lake showing where the host rock is a "black hornblende granite".

According to Collins and Swan, "four miles N 40° E of Allison Bay, yellow stains of alteration products were observed over an area of 30 feet by 400 feet, and, at one locality where surface blasting had been undertaken, a radioactive anomaly was found that reached a maximum of 10 times background on a geiger ratemeter". The host rocks are granite.

Little is known of the structural control for the occurrences noted by Godfrey. They may be localized along the axes of isoclinal folds close to major cross faults. The Fishing Lake, Leggo Lake and Allison Bay deposits are located along fracture zones striking east-west to northeast-southwest.

Detailed Geology of Permits 132, 133 and 134

The area included by permits 132, 133 and 134 was mapped on a reconnaissance scale by Riley, in 1958. Only a very general impression of the rock types present can be gained from Riley's mapping. The rock types underlying the permits (according to Riley) are shown on Map 3.
About 20% of the permit area is underlain by metasediments, 50% by ortho and paragneisses, 15% by granitic rocks. The remainder is underlain by rocks which Riley calls - undivided plutonic and metamorphic rocks (Map 3). Foliations strike generally northeast-southwest. Dips are steep and to the northwest or southeast.

The regional structure of the area is shown on Map 2 (attached). The Allan fault strikes NE-SW through the eastern part of the permit area. The Allan fault is characterized by a wide zone of mylonites, which are at least several miles in width where mapped further north by Godfrey. A second structural system, comprising a set of sub-parallel east-west cross faults, transects the Allan fault mylonite zone within the permit area (see Map 5).

About four miles north of Sand Point, a strong system of ENE-WSW faults intersects the shore-line of Lake Athabasca. This system continues west through Loutit Lake. This could be an extension of the Beaverlodge system. It is possible that the Athabasca mylonite zone and the Allan fault intersect, and, in part, merge in the region of the permits.

A system of generally north-south trending minor faults occur over the whole area. These faults appear to cut all other structures and are probably tensional in nature.

ECONOMIC POTENTIAL

In all likelihood, the rocks in the NE Corner are equivalents of the Tazin group, which is the host rock for most of the uranium deposits in the Beaverlodge area of Saskatchewan. The metamorphic grades and ages are the same.

Only a small portion of the NE Corner has been mapped in detail and the remainder has been prospected in only a very cursory fashion. It is thought highly significant that, in spite of the lack of detailed work, so many important uranium deposits have been found to date in the area.
The geological environment of permits 132, 133 and 134 is considered highly favourable for the localization of uranium, for the reasons outlined below:

The structural environment is almost identical with that of the Beaverlodge area, where the NE-SW Athabasca system of mylonites is transected by a strong zone of E-W faults. Within permits 132, 133 and 134 an important system of E-W faults similarly cuts a wide NE-SW mylonite belt (the Allan fault).

The Athabasca system can be extrapolated to extend beneath Lake Athabasca, just south of Fidler Point, and may merge with the Allan fault system in the region of the permits.

The important controls of mineralization in both the Beaverlodge area and the NE Corner are structural, i.e. faults; and fold axes close to faults. The permit areas are characterized by a very high density of cross cutting faults. Not enough detailed work has been done to comment on the frequency of folding in the permit area. It can be stated, however, that isoclinal folding is prevalent throughout all of the Precambrian in the NE Corner. The metasedimentary areas of the permits should be particularly favourable because of their susceptibility to this type of folding.

Mylonization is probably very important. There is evidence to suggest that the uranium may be derived from the mylonites and subsequently localized in cross faults.

Uranium showings occur on permit 123 and copper on permit 124, to the south. All the showings occur along the strike of the Allan fault, but appear to be localized near N-S and NW-SE fault intersections. The deposits change from copper sulphides, through silver to uranium, along strike. The association of copper and silver with uranium on a regional scale, is common throughout the world.

It is understood that a uranium showing occurs north of Flett Lake. The exact location is not known.
RECOMMENDED PLAN FOR EXPLORATION

The first phase of the exploration program should be to obtain a fairly detailed picture of the geology of the permit areas. Mapping and prospecting could be carried out by a two man party, with supervision, over a three month period. Mapping should be done in greater detail in the neighbourhood of favourable structures. Scintillometers should be carried on all traverses.

The percentage of rock outcrop in the area is high. However, to supplement the geological and radiometric coverage of the area, soil or vegetation (geochemical or biogeochemical) samples could be collected. These could be taken at intervals of about 500 feet. The cost at this stage would be simply that of the sample bags. The samples could be analysed later for uranium, and possibly copper, if this is deemed feasible.

It is suggested that an airborne scintillometer (spectrometric) survey be arranged to cover an area which includes the whole of permit 132, and the southeast portions of permits 133 and 134, as shown on Map 3. This comprises an area of about 120 square miles. The remainder of permits 133 and 134 should be flown if the first phase of the airborne survey proves successful. It should be emphasized at this point that, even with the most modern equipment, an airborne radiometric survey is still a reconnaissance tool. Its use would in no way preclude the work of the ground party. It could considerably accelerate the exploration by outlining targets for investigation.

The costs are estimated below, for three phases of exploration. If a find of any significance is made in the course of phase 1, then phase 2 should be considered. To complete phase 2 the field season can be extended as necessary, or the number of men increased.

The operations indicated in phase 3 are, of course, contingent upon the success of the previous phases.
COSTS

Phase 1

Equipment - purchase (camp, boat, motor etc) $1,500
   - rental (scintillometers, radio) $1,500
Camp operating costs $3,000
Salaries - Mapping, prospecting & supervision $8,000

Airborne radiometric survey - cost is based on a rate of $10.50/line mile; 1/8 mile line spacing. $10,000

$24,000

Phase 2

Airborne radiometric survey - remaining 100 square miles $8,500
Detailed mapping $2,000
Detailed ground geophysics $2,000
Trenching, sampling, assays and supervision $2,000

$14,500

Optional:
Geochemical analyses $2,000

Phase 3

Diamond drilling $10,000
Supervision $3,000
Sampling and assays $1,000
Camp $2,000

$16,000

Total: $56,500

Respectfully submitted,

Anthony Rich John A. Greig

AMENDED SCHEDULE

to Quartz Mineral Exploration Permit No. 132

IN TOWNSHIP ONE HUNDRED AND FIFTEEN (115), RANGE FIVE (5),
WEST OF THE FOURTH (4) MERIDIAN:

Sections Four (4) to Eleven (11) inclusive, Sections Fourteen (14), Fifteen (15), Sixteen (16), Twenty-two (22), Twenty-five (25), Twenty-six (26) and Twenty-seven (27) and Sections Thirty-three (33) to Thirty-six (36) inclusive;

AND

IN TOWNSHIP ONE HUNDRED AND FIFTEEN (115), RANGE SIX (6),
WEST OF THE FOURTH (4) MERIDIAN:

Sections One (1) and Two (2), Sections Eleven (11) to Fourteen (14) inclusive, Sections Twenty-three (23) to Twenty-seven (27) inclusive and Sections Thirty-four (34) and Thirty-five (35);

containing an area of Twenty Thousand, Four Hundred and Eighty (20,480) acres, more or less.

Dated this 1st day of April, 1970;

Director of Minerals
Mr. Ralph Gilmore
Mr. Sullivan

Asamera is still exploring our 22 permit—hope to have a definitive answer soon—so don't be in too much of a hurry to activate cancellation or posting to Crown revenue. I will call you every week to report on Asamera.
